TABLES OF COTTON-FIBER TENSILE STRENGTH FOR USE IN MAKING  
PRESSLEY TESTS 1/

The Pressley instrument is widely used in the cotton industry for testing cotton fibers for tensile strength. In making strength tests with this instrument there are various calculations involved in obtaining the strength value in terms of pounds per square inch of fibers. The customary procedure has been to obtain an index by dividing the Pressley beam reading by the weight of the bundle of fibers and then calculate the tensile strength (1,000 lbs. per sq. inch) by the following formula:

$$\text{Tensile strength (1,000 lbs. per sq. in.)} = (\text{index} \times 10.8116) - 0.12$$

To reduce the time involved in making Pressley calculations, a set of tables has been prepared to provide the tensile strength values directly from the Pressley beam reading and the weight of the fiber bundle. These tables are given on pages 2 to 23 inclusive of this report. The formula used for calculating data for these tables is as follows:

$$\text{Tensile strength (1,000 lbs. per sq. in.)} =$$

$$\frac{\text{Pressley beam reading} \times 10.8116}{\text{Bundle wt. (in milligrams)}} - 0.12$$

The tables are used as standard procedure for Pressley tests in all of the fiber laboratories operated by the Cotton Branch. Other fiber laboratories may find the tables useful in reducing the time required for calculating tensile strength values.

In the event the Pressley beam reading or the fiber bundle weight do not fall within these tables, the above formula can be used to calculate the strength value.

If the Pressley index is desired, that value may be obtained from a conversion table that has been included also which shows Pressley indices for various 1,000 pounds per square inch values (page 24).
